

## Assignment 2f - Design Review (1x2)

Yi Zeng, Annabelle Martin, Claudia Soebagijo, Kevin Wu, Sahana Hegde

### Section A

#### Design Review:

- Why this design and these tasks?
  - Our designs include a Bayminni bot and a mobile application. The idea is that users could log their symptoms by conversing with Baymini, and the mobile app would present summaries, trends, and triggers to them. So the Baymini is the input to which users can directly provide, and the mobile app presents the output of users' data in a structured and meaningful way. The rationale behind those tasks is to address doctor-patient communication and provide easier ways to log symptoms. When users visit their doctors, the mobile app will provide their health data in a way that makes it easier for doctors to understand, enabling them to provide more personalized treatment plans. During flare-ups, users could log their symptoms by speaking rather than typing or writing. Therefore, it reduces the efforts of logging.
- What makes the design better suited to the people for whom you are targeting your design?
  - This design is better suited for individuals with chronic illnesses because it prioritizes accessibility, low-effort interaction, and communication support during difficult moments. Many users experience flare-ups, fatigue, or cognitive overload and may struggle to manually type detailed symptom logs into a traditional health-tracking app. By allowing users to naturally speak to Baymini, the system reduces physical and mental effort while making symptom tracking more immediate and accurate.
- Why are these tasks more compelling than the others?
  - These tasks were chosen because they represent common, high-impact situations that users with chronic conditions frequently encounter in their daily lives. Logging symptoms during flare-ups is especially compelling because flare-ups are often physically and emotionally overwhelming, making traditional manual logging methods difficult to use in the moment. Voice-based symptoms logging reduces this burden and allows users to capture experiences more naturally and accurately. Explaining conditions to doctors is another highly important task, as many users struggle to summarize long-term health experiences in short medical appointments.
- What role does GenAI play in your design, if any, and why?
  - For logging symptoms during flare-ups, both Baymini and the mobile app allow users to record how they're feeling by voice ("Hey Baymini, I'm feeling xyz"). GenAI automatic speech recognition (ASR), like OpenAI's Whisper, can be used to accurately transcribe speech to text. This allows users to quickly log their symptoms in an unstructured format with minimal user interaction.

- For explaining conditions to doctors, Baymini and the mobile app take data from the past x days/weeks/months and use genAI to accurately summarize the user's symptoms, trends, triggers, etc., in a way that doctors can understand. This helps users communicate their conditions more clearly.

## Design

### Task 1: Logging Symptoms during a flare-up

## Task 2: Explaining conditions to the doctors

User has a doctor's appointment tomorrow

| user  | symptoms | HR | Pain |
|-------|----------|----|------|
| day 1 | ~        | ~  | ~    |
| day 2 | ~        | ~  | ~    |
| ...   |          |    |      |

baymini has a database of user health data

the data can be compiled for the user, an employer, or a doctor or specialist.

The data is shown to a doctor

The doctor and user talk about the data

The doctor proposes next steps (tests, diagnoses)
